Mudcard

- **At the very beginning of the lecture when you were speaking about continuous column visualization, and changing the histogram to show more information, I did not understand how to two below lines of codes changed the histograms**
  - Just try it on the notebook to figure it out and read the histogram manual. :)
- **Are we supposed to use the defaulted figsize for all the graphs?**
  - usually the answer to such questions is no.
  - the default figsize might work most of the time but sometimes you'll have to change it.
  - I do not use the default figsize in the lecture notes.
  - I make the figures smaller than default because I need to increase the font size to make it readable in class
  - you need to experiment to figure out what works
  - e.g., you might need different figure sizes / font sizes, etc. for the report and the presentation
- **when to use logs**
  - if the queantity you plot varies over multiple orders of magnitudes
- **The muddiest part of the lecture was bring able to decide which type of data visualization to use based on whether the variables are continuous, ordinal, or categorical. I feel confident in classifying variables as such, but once I do that, I don't necessarily know which chart to use.**
  - rewatch the video recording and makes notes on this
  - I described 1 to 3 figure types based on column properties
- **How do we make the x-axis log?**
  - plt.semilogx()
  - or search the matplotlib manual and/or stackoverflow and/or chatGPT or your favorite generative AI tool
- **Interpretation of Violin Plots and Scatter Matrices**
  - read more about these figure types in the resources I linked at the end of the lecture
- **Heat maps, bins, and changing scales to log were difficult to understand**
  - experiment with the code in the notebook

Split iid data

By the end of this lecture, you will be able to

- apply basic split to iid datasets
- apply k-fold split to iid datasets
- apply stratified splits to imbalanced data

The supervised ML pipeline

The goal: Use the training data (X and y) to develop a model which can accurately predict the target variable (y_new') for previously unseen data (X_new).

1. Exploratory Data Analysis (EDA): you need to understand your data and verify that it doesn't contain errors

- do as much EDA as you can!

2. Split the data into different sets: most often the sets are train, validation, and test (or holdout)

- practitioners often make errors in this step!
- you can split the data randomly, based on groups, based on time, or any other non-standard way if necessary to answer your ML question

3. Preprocess the data: ML models only work if X and Y are numbers! Some ML models additionally require each feature to have 0 mean and 1 standard deviation (standardized features)

- often the original features you get contain strings (for example a gender feature would contain 'male', 'female', 'non-binary', 'unknown') which needs to transformed into numbers
- often the features are not standardized (e.g., age is between 0 and 100) but it needs to be standardized

4. Choose an evaluation metric: depends on the priorities of the stakeholders

- often requires quite a bit of thinking and ethical considerations

5. Choose one or more ML techniques: it is highly recommended that you try multiple models

- start with simple models like linear or logistic regression
- try also more complex models like nearest neighbors, support vector machines, random forest, etc.

6. Tune the hyperparameters of your ML models (aka cross-validation)

- ML techniques have hyperparameters that you need to optimize to achieve best performance
- for each ML model, decide which parameters to tune and what values to try
- loop through each parameter combination
    - train one model for each parameter combination
    - evaluate how well the model performs on the validation set
- take the parameter combo that gives the best validation score
- evaluate that model on the test set to report how well the model is expected to perform on previously unseen data

7. Interpret your model: black boxes are often not useful

- check if your model uses features that make sense (excellent tool for debugging)
- often model predictions are not enough, you need to be able to explain how the model arrived to a particular prediction (e.g., in health care)

Why do we split the data?

- we want to find the best hyper-parameters of our ML algorithms
    - fit models to training data
    - evaluate each model on validation set
    - we find hyper-parameter values that optimize the validation score
- we want to know how the model will perform on previously unseen data
    - apply our final model on the test set

We need to split the data into three parts!

Recap from the second lecture

- **the learner's input**
    - Domain set $\mathcal{X}$ - a set of objects we wish to label.
    - Label set $\mathcal{Y}$ - a set of possible labels.
    - Training data $S = ((x_1, y_1), \ldots, (x_m, y_m))$ - a finite sequence of pairs from $\mathcal{X}$, $\mathcal{Y}$. This is what the learner has access to.
        - $X = (x_1, \ldots, x_m)$ is the feature matrix which is usually a 2D matrix, and $Y = (y_1, \ldots, y_m)$ is the target variable which is a vector.
- let's denote the probability distribution over $\mathcal{X}$ by D.
- let's assume there is some correct labeling function $f : \mathcal{X} \to \mathcal{Y}$.
- **a training example is then generated by sampling x_i from D, and the label y_i is generated using f.**

I.I.D. assumption

- **the i.i.d. assumption**: the examples in the training set are independently and identically distributed according to D
    - every x_i is freshly sampled from D and then labelled by f
    - that is, x_i and y_i are picked independently of the other instances
    - S is a window through which the learner gets partial info about D and the labeling function f
    - the larger the sample gets, the more likely it is to reflect more accurately D and f
- examples of not iid data:
    - data generated by time-dependent processes
    - data has group structure (samples collected from e.g., different subjects, experiments, measurement devices)

Split iid data

By the end of this lecture, you will be able to

- **apply basic split to iid datasets**
- apply k-fold split to iid datasets
- apply stratified splits to imbalanced data

Splitting strategies for iid data: basic approach

- 60% train, 20% validation, 20% test for small datasets
- 98% train, 1% validation, 1% test for large datasets
    - if you have 1 million points, you still have 10000 points in validation and test which is plenty to assess model performance

Let's work with the adult data!

In [1]:
```
import pandas as pd
import numpy as np
from sklearn.model_selection import train_test_split

df = pd.read_csv('data/adult_test.csv')

# let's separate the feature matrix X, and target variable y
y = df['gross-income'] # remember, we want to predict who earns more than 50k or less than 50k
X = df.loc[:, df.columns != 'gross-income'] # all other columns are features
print(y)
print(X.head())
```

```
0         <=50K.
1         <=50K.
2          >50K.
3          >50K.
4         <=50K.
          ...
16276     <=50K.
16277     <=50K.
16278     <=50K.
16279     <=50K.
16280      >50K.

In [2]:
```
help(train_test_split)
```

```
Help on function train_test_split in module sklearn.model_selection._split:

train_test_split(*arrays, test_size=None, train_size=None, random_state=None, shuffle=True, stratify=None)
    Split arrays or matrices into random train and test subsets.

    Quick utility that wraps input validation,
    ``next(ShuffleSplit().split(X, y))``, and application to input data
    into a single call for splitting (and optionally subsampling) data into a
    one-liner.

    Read more in the :ref:`User Guide <cross_validation>`.

    Parameters
    ----------
    *arrays : sequence of indexables with same length / shape[0]
        Allowed inputs are lists, numpy arrays, scipy-sparse
        matrices or pandas dataframes.

    test_size : float or int, default=None
        If float, should be between 0.0 and 1.0 and represent the proportion
        of the dataset to include in the test split. If int, represents the
        absolute number of test samples. If None, the value is set to the
        complement of the train size. If ``train_size`` is also None, it will
        be set to 0.25.

    train_size : float or int, default=None
        If float, should be between 0.0 and 1.0 and represent the
        proportion of the dataset to include in the train split. If
        int, represents the absolute number of train samples. If None,
        the value is automatically set to the complement of the test size.

    random_state : int, RandomState instance or None, default=None
        Controls the shuffling applied to the data before applying the split.
        Pass an int for reproducible output across multiple function calls.
        See :term:`Glossary <random_state>`.

    shuffle : bool, default=True
        Whether or not to shuffle the data before splitting. If shuffle=False
        then stratify must be None.

    stratify : array-like, default=None
        If not None, data is split in a stratified fashion, using this as
        the class labels.
        Read more in the :ref:`User Guide <stratification>`.

    Returns
    -------
    splitting : list, length=2 * len(arrays)
        List containing train-test split of inputs.

        .. versionadded:: 0.16
            If the input is sparse, the output will be a
            ``scipy.sparse.csr_matrix``. Else, output type is the same as the
            input type.

    Examples
    --------
    >>> import numpy as np
    >>> from sklearn.model_selection import train_test_split
    >>> X, y = np.arange(10).reshape((5, 2)), range(5)
    >>> X
    array([[0, 1],
           [2, 3],
           [4, 5],
           [6, 7],
           [8, 9]])
    >>> list(y)
    [0, 1, 2, 3, 4]

    >>> X_train, X_test, y_train, y_test = train_test_split(
    ...     X, y, test_size=0.33, random_state=42)
    ...
    >>> X_train
    array([[4, 5],
           [0, 1],
           [6, 7]])
    >>> y_train
    [2, 0, 3]
    >>> X_test
```

```
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]

>>> train_test_split(y, shuffle=False)
[[0, 1, 2], [3, 4]]
```

In [3]:
```python
random_state = 42

# first split to separate out the training set
X_train, X_other, y_train, y_other = train_test_split(X,y,\
                    train_size = 0.6,random_state = random_state)
print('training set:',X_train.shape, y_train.shape) # 60% of points are in train
print(X_other.shape, y_other.shape) # 40% of points are in other

# second split to separate out the validation and test sets
X_val, X_test, y_val, y_test = train_test_split(X_other,y_other,\
                    train_size = 0.5,random_state = random_state)
print('validation set:',X_val.shape, y_val.shape) # 20% of points are in validation
print('test set:',X_test.shape, y_test.shape) # 20% of points are in test

print(X_train.head())
```

```

13058             0             0              55   United-States
```

Randomness due to splitting

- the model performance, validation and test scores will change depending on which points are in train, val, test
  - inherent randomness or uncertainty of the ML pipeline
- change the random state a couple of times and repeat the whole ML pipeline to assess how much the random splitting affects your test score
  - you would expect a similar uncertainty when the model is deployed

Quiz 1

What's the second train_test_split line if you want to end up with 60-20-20 in train-val-test? Print out the sizes of X_train, X_val, X_test to verify!

In [4]:
```python
X_other, X_test, y_other, y_test = train_test_split(X,y,\
                    train_size = 0.8,random_state=random_state)
# add your line below and chose the correct solution from canvas
```

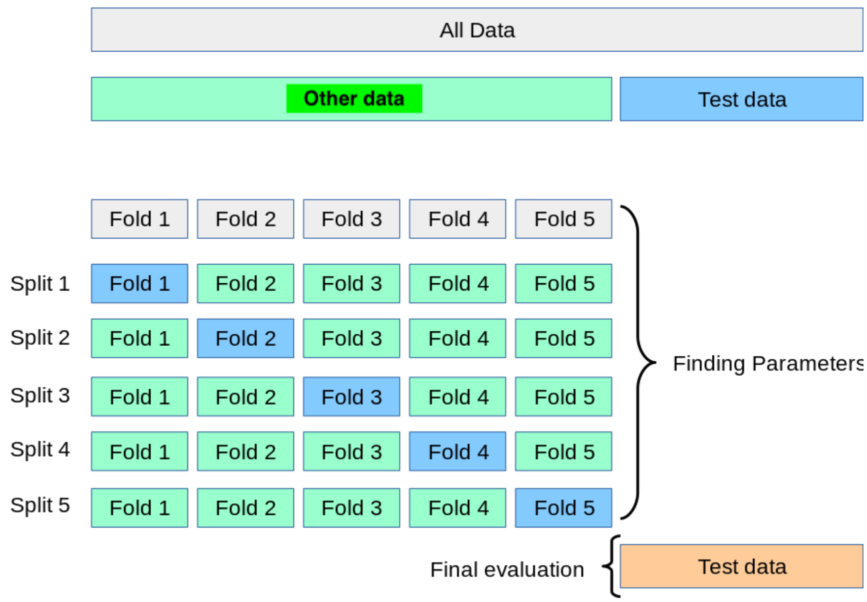
Split iid data

By the end of this lecture, you will be able to

- apply basic split to iid datasets

- **apply k-fold split to iid datasets**
- apply stratified splits to imbalanced data

Other splitting strategy for iid data: k-fold splitting



In [5]:
```
from sklearn.model_selection import KFold
help(KFold)
```

```
Help on class KFold in module sklearn.model_selection._split:

class KFold(_BaseKFold)
 |  KFold(n_splits=5, *, shuffle=False, random_state=None)
 |
 |  K-Folds cross-validator
 |
 |  Provides train/test indices to split data in train/test sets. Split
 |  dataset into k consecutive folds (without shuffling by default).
 |
 |  Each fold is then used once as a validation while the k - 1 remaining
 |  folds form the training set.
 |
 |  Read more in the :ref:`User Guide <k_fold>`.
 |
 |  Parameters
 |  ----------
 |  n_splits : int, default=5
 |      Number of folds. Must be at least 2.
 |
 |      .. versionchanged:: 0.22
 |          ``n_splits`` default value changed from 3 to 5.
 |
 |  shuffle : bool, default=False
 |      Whether to shuffle the data before splitting into batches.
 |      Note that the samples within each split will not be shuffled.
 |
 |  random_state : int, RandomState instance or None, default=None
 |      When `shuffle` is True, `random_state` affects the ordering of the
 |      indices, which controls the randomness of each fold. Otherwise, this
 |      parameter has no effect.
 |      Pass an int for reproducible output across multiple function calls.
 |      See :term:`Glossary <random_state>`.
 |
 |  Examples
 |  --------
 |  >>> import numpy as np
 |  >>> from sklearn.model_selection import KFold
 |  >>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
 |  >>> y = np.array([1, 2, 3, 4])
 |  >>> kf = KFold(n_splits=2)
 |  >>> kf.get_n_splits(X)
 |  2
 |  >>> print(kf)
 |  KFold(n_splits=2, random_state=None, shuffle=False)
 |  >>> for i, (train_index, test_index) in enumerate(kf.split(X)):
 |  ...     print(f"Fold {i}:")
 |  ...     print(f"  Train: index={train_index}")
 |  ...     print(f"  Test:  index={test_index}")
 |  Fold 0:
 |    Train: index=[2 3]
 |    Test:  index=[0 1]
 |  Fold 1:
 |    Train: index=[0 1]
 |    Test:  index=[2 3]
 |
 |  Notes
 |  -----
 |  The first ``n_samples % n_splits`` folds have size
 |  ``n_samples // n_splits + 1``, other folds have size
 |  ``n_samples // n_splits``, where ``n_samples`` is the number of samples.
 |
 |  Randomized CV splitters may return different results for each call of
 |  split. You can make the results identical by setting `random_state`
 |  to an integer.
 |

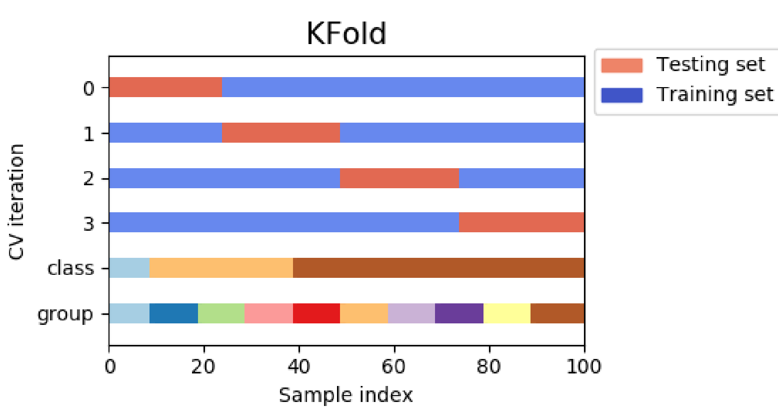
How many splits should I create?

- tough question, 3-5 is most common
- if you do n splits, n models will be trained, so the larger the n, the most computationally intensive it will be to train the models
- KFold is usually better suited to small datasets
- KFold is good to estimate uncertainty due to random splitting of train and val, but it is not perfect
    - the test set remains the same

Why shuffling iid data is important?

- by default, data is not shuffled by Kfold which can introduce errors!



Quiz 2

Given the labels below, what are the balances of each class?

y = [0,0,0,2,2,0,0,2,0,1]

Split iid data

By the end of this lecture, you will be able to

- apply basic split to iid datasets
- apply k-fold split to iid datasets
- **apply stratified splits to imbalanced data**

Imbalanced data

- imbalanced data: only a small fraction of the points are in one of the classes, usually ~5% or less but there is no hard limit here
- examples:
    - people visit a bank's website. do they sign up for a new credit card?
        - most customers just browse and leave the page
        - usually 1% or less of the customers get a credit card (class 1), the rest leaves the page without signing up (class 0).
    - fraud detection
        - only a tiny fraction of credit card payments are fraudulent
    - rare disease diagnosis
- the issue with imbalanced data:
    - if you apply train_test_split or KFold, you might not have class 1 points in one of your sets by chance
    - this is what we need to fix

Solution: stratified splits

In [7]:
```
df = pd.read_csv('data/imbalanced_data.csv')

X = df[['feature1','feature2']]
y = df['y']

print(y.value_counts())
```

```
y
0    990
1     10
Name: count, dtype: int64
```

In [8]:
```
# 4 and 10

random_state = 4

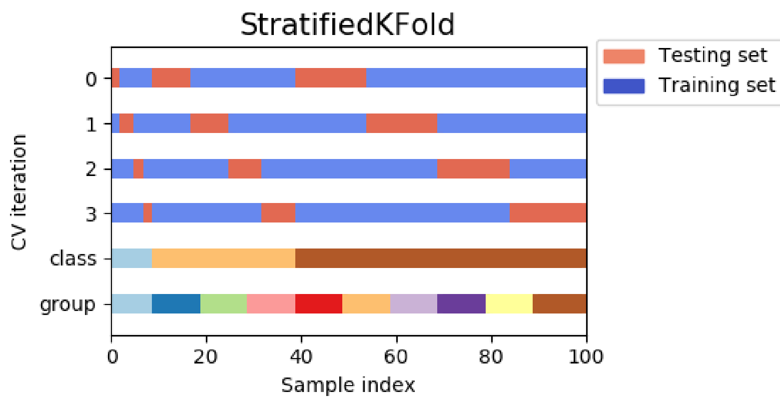
X_train, X_other, y_train, y_other = train_test_split(X,y,train_size = 0.6,random_state=random_state)
X_val, X_test, y_val, y_test = train_test_split(X_other,y_other,train_size = 0.5,random_state=random_state)

print('**balance without stratification:**')
# a variation on the order of 1% which would be too much for imbalanced data!
print(np.unique(y_train,return_counts=True))
print(np.unique(y_val,return_counts=True))
print(np.unique(y_test,return_counts=True))

X_train, X_other, y_train, y_other = train_test_split(X,y,train_size = 0.6,stratify=y,random_state=random_state)
X_val, X_test, y_val, y_test = train_test_split(X_other,y_other,train_size = 0.5,stratify=y_other,random_state=ra
print('**balance with stratification:**')
# very little variation (in the 4th decimal point only) which is important if the problem is imbalanced
print(np.unique(y_train,return_counts=True))
print(np.unique(y_val,return_counts=True))
print(np.unique(y_test,return_counts=True))
```

```
**balance without stratification:**
(array([0, 1]), array([591,   9]))
(array([0]), array([200]))
(array([0, 1]), array([199,   1]))
**balance with stratification:**
(array([0, 1]), array([594,   6]))
(array([0, 1]), array([198,   2]))
(array([0, 1]), array([198,   2]))
```

Stratified folds



In [9]:
```python
from sklearn.model_selection import StratifiedKFold
help(StratifiedKFold)
```

```
Help on class StratifiedKFold in module sklearn.model_selection._split:

class StratifiedKFold(_BaseKFold)
 |  StratifiedKFold(n_splits=5, *, shuffle=False, random_state=None)
 |
 |  Stratified K-Folds cross-validator.
 |
 |  Provides train/test indices to split data in train/test sets.
 |
 |  This cross-validation object is a variation of KFold that returns
 |  stratified folds. The folds are made by preserving the percentage of
 |  samples for each class.
 |
 |  Read more in the :ref:`User Guide <stratified_k_fold>`.
 |
 |  Parameters
 |  ----------
 |  n_splits : int, default=5
 |      Number of folds. Must be at least 2.
 |
 |      .. versionchanged:: 0.22
 |          ``n_splits`` default value changed from 3 to 5.
 |
 |  shuffle : bool, default=False
 |      Whether to shuffle each class's samples before splitting into batches.
 |      Note that the samples within each split will not be shuffled.
 |
 |  random_state : int, RandomState instance or None, default=None
 |      When `shuffle` is True, `random_state` affects the ordering of the
 |      indices, which controls the randomness of each fold for each class.
 |      Otherwise, leave `random_state` as `None`.
 |      Pass an int for reproducible output across multiple function calls.
 |      See :term:`Glossary <random_state>`.
 |
 |  Examples
 |  --------
 |  >>> import numpy as np
 |  >>> from sklearn.model_selection import StratifiedKFold
 |  >>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
 |  >>> y = np.array([0, 0, 1, 1])
 |  >>> skf = StratifiedKFold(n_splits=2)
 |  >>> skf.get_n_splits(X, y)
 |  2
 |  >>> print(skf)
 |  StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
 |  >>> for i, (train_index, test_index) in enumerate(skf.split(X, y)):
 |  ...     print(f"Fold {i}:")
 |  ...     print(f"  Train: index={train_index}")
 |  ...     print(f"  Test:  index={test_index}")
 |  Fold 0:
 |    Train: index=[1 3]
 |    Test:  index=[0 2]
 |  Fold 1:
 |    Train: index=[0 2]
 |    Test:  index=[1 3]
 |
 |  Notes
 |  -----
 |  The implementation is designed to:
 |
 |  * Generate test sets such that all contain the same distribution of
 |    classes, or as close as possible.
 |  * Be invariant to class label: relabelling ``y = ["Happy", "Sad"]`` to
 |    ``y = [1, 0]`` should not change the indices generated.
 |  * Preserve order dependencies in the dataset ordering, when
 |    ``shuffle=False``: all samples from class k in some test set were
 |    contiguous in y, or separated in y by samples from classes other than k.
 |  * Generate test sets where the smallest and largest differ by at most one
 |    sample.
 |
 |  .. versionchanged:: 0.22
 |      The previous implementation did not follow the last constraint.
 |

 |  Method resolution order:
 |      StratifiedKFold
```

```
 |      _BaseKFold
 |      BaseCrossValidator
 |      sklearn.utils._metadata_requests._MetadataRequester
 |      builtins.object
 |
 |  Methods defined here:
 |
 |  __init__(self, n_splits=5, *, shuffle=False, random_state=None)
 |      Initialize self.  See help(type(self)) for accurate signature.
 |
 |  split(self, X, y, groups=None)
 |      Generate indices to split data into training and test set.
 |
 |      Parameters
 |      ----------
 |      X : array-like of shape (n_samples, n_features)
 |          Training data, where `n_samples` is the number of samples
 |          and `n_features` is the number of features.
 |
 |          Note that providing ``y`` is sufficient to generate the splits and
 |          hence ``np.zeros(n_samples)`` may be used as a placeholder for
 |          ``X`` instead of actual training data.
 |
 |      y : array-like of shape (n_samples,)
 |          The target variable for supervised learning problems.
 |          Stratification is done based on the y labels.
 |
 |      groups : object
 |          Always ignored, exists for compatibility.
 |
 |      Yields
 |      ------
 |      train : ndarray
 |          The training set indices for that split.
 |
 |      test : ndarray
 |          The testing set indices for that split.
 |
 |      Notes
 |      -----
 |      Randomized CV splitters may return different results for each call of
 |      split. You can make the results identical by setting `random_state`
 |      to an integer.
 |

```
 |
 |  get_metadata_routing(self)
 |      Get metadata routing of this object.
 |
 |      Please check :ref:`User Guide <metadata_routing>` on how the routing
 |      mechanism works.
 |
 |      Returns
 |      -------
 |      routing : MetadataRequest
 |          A :class:`~utils.metadata_routing.MetadataRequest` encapsulating
 |          routing information.
 |
 |  ----------------------------------------------------------------------
 |  Class methods inherited from sklearn.utils._metadata_requests._MetadataRequester:
 |
 |  __init_subclass__(**kwargs) from abc.ABCMeta
 |      Set the ``set_{method}_request`` methods.
 |
 |      This uses PEP-487 [1]_ to set the ``set_{method}_request`` methods. It
 |      looks for the information available in the set default values which are
 |      set using ``__metadata_request__*`` class attributes, or inferred
 |      from method signatures.
 |
 |      The ``__metadata_request__*`` class attributes are used when a method
 |      does not explicitly accept a metadata through its arguments or if the
 |      developer would like to specify a request value for those metadata
 |      which are different from the default ``None``.
